Keywords:
Diffuse hair loss
Serum ferritin
Iron deficiency

A B S T R A C T
Context: Iron deficiency leads to disruption of hair follicle as elemental Iron is involved in various physiological processes within the hair follicle.
Aim: The aim of this study is to evaluate if a correlation exists between decreased serum ferritin levels and the most common causes of diffuse hair fall.
Setting and Design: This was a cross sectional study conducted at a teaching hospital and research center.
Materials and Methods: 60 female patients aged between 15-45 years complaining of diffuse hair loss are taken into consideration.
Results: A significant correlation was found between decreased body iron stores (as measured by serum ferritin levels) and diffuse hair loss. 65% of the subjects were found to be in iron deficient state, 20% in iron depleted state, 8.33% with adequate serum ferritin levels but lower than the required for normal hair cycle, and 3.66% with normal ferritin levels.
Conclusion: Diffuse hair loss was found to be associated with significantly decreased serum ferritin levels.

1. Introduction

1. Diffuse hair fall is one of the most common problem seen in women.
2. An average normal scalp has about 1,00,000 hairs, with approximately 86% being in anagen (the active growth phase), 1% in catagen (phase of involution), and 13% in telogen (the resting stage). Loss of 100-150 telogen hair is considered as normal.
3. Telogen effluvium (TE), whether acute or chronic (i.e. of more than 6 months duration) followed by female pattern hair loss (FPHL) is the most common cause of diffuse hair loss.
4. In both conditions, low iron stores is considered a possible contributing factor, thus assessment of serum ferritin levels is generally recommended as part of the routine investigation.
5. Under steady-state conditions, serum ferritin levels are the most convenient laboratory test to estimate body iron stores and how well its level correlates with diffuse hair loss is explained in this article.

2. Iron

1. Iron is involved in many processes within the hair follicle, suggesting that iron deficiency could disrupt hair synthesis.
2. Within cells, iron is stored complexed to protein as ferritin or hemosiderin.
3. Ferritin is a highly conserved protein complex that plays an important role in iron storage and is recognized as the main iron-binding protein in non-erythroid cells.
4. Generally, serum ferritin is directly related to intracellular ferritin and thus to the total body iron stores.

3. Stages of Iron Deficiency

1. The progression to iron deficiency can be divided into 3 stages
2. The first stage is negative iron balance, in which demands for (or losses of) iron exceed the body’s ability to absorb iron from the diet. During this period, iron stores as reflected by the serum ferritin level or by the appearance of stainable iron on bone marrow aspirations decrease.

3. As long as iron stores are present and can be mobilized, the serum iron, total iron binding capacity (TIBC), and red cell protoporphyrin levels remain within normal limits.

4. At this stage red cell morphology and indices are normal.

5. When iron stores become depleted, the serum iron begins to fall. Gradually, the TIBC increases, as do red cell protoporphyrin levels.

6. By definition, marrow iron stores are absent when the serum ferritin level is less than 15 microgram/L.

7. As long as the serum iron remains within the normal range, haemoglobin synthesis is unaffected despite the dwindling iron stores.

8. Once the transferrin saturation falls to 15-20%, haemoglobin synthesis become impaired. This is a period of iron deficient erythropoiesis. Gradually the haemoglobin begins to fall reflecting iron deficiency anaemia.

9. The most common causes of iron deficiency are menstrual blood loss and pregnancy in premenopausal women.

4. Materials and Methods

4.1. Study design

This was cross sectional study.

4.2. Study source

This study was conducted in the Department of Dermatology, Venereology and Leprosy, Shadan Institute of Medical Sciences, Teaching Hospital and Research Center, Hyderabad, Telangana, India from January 2019 to January 2020.

4.3. Sample size

Total of 60 female patients aged between 15-45 years were recruited in the study.

4.4. Inclusion criteria

All the consenting female participants of age group 15–45 years, with chronic diffuse hair loss, acute and chronic telogen effluvium.

4.5. Exclusion criteria

1. Participants who did not give consent.

2. Patients who were on iron therapy.

3. Patients undergoing gastrointestinal/scalp surgeries.

4. Patients suffering from trichotillomania.

5. Patients with hormonal abnormalities.

6. Patients who were on medications for systemic disorders.

4.6. Data collection

An informed and written consent was obtained from each patient. After eliciting detailed history a complete physical and clinical examination of each patient was carried out and only those fulfilling inclusion criteria were included in the study. Diagnosis of TE/ChronicTE and FPHL was made on clinical examination and by performing hair-pull test.

4.7. Laboratory investigations

Sample collection: 3 ml of venous blood was collected from all participants for estimation of serum ferritin by chemiluminescence immuno assay (CLIA).

5. Results

Here, in this study, based on the serum ferritin levels, the patients are grouped into four categories as follows:

If we analyse these results percentage wise it can be represented as follows.

Fig. 1: Percentage wise distribution of serum ferritin levels

6. Discussion

1. This study was done to evaluate if a correlation exists between the most common causes of diffuse hair loss
Table 1:

<table>
<thead>
<tr>
<th>Group Name</th>
<th>Serum Ferritin level</th>
<th>No. of patients in the group</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Iron Deficiency state</td>
<td>≤12 μg/L</td>
<td>39</td>
</tr>
<tr>
<td>2. Iron Depletion state</td>
<td>13–20 μg/L</td>
<td>12</td>
</tr>
<tr>
<td>3. Serum Ferritin level adequate but lower than</td>
<td>21–70 μg/L</td>
<td>5</td>
</tr>
<tr>
<td>required for normal hair cycle</td>
<td></td>
<td></td>
</tr>
<tr>
<td>4. Normal Ferritin level</td>
<td>≥71 μg/L</td>
<td>4</td>
</tr>
</tbody>
</table>

7. Conclusion

1. Significant relation was detected between decreased tissue iron stores and the most common causes of diffuse hair loss (including both telogen effluvium and female pattern hair loss)
2. However, further scientific studies with larger sample sizes are required to associate different etiological factors and iron deficiency leading to hair loss.

8. Source of Funding

None.

9. Conflicts of interest

None.
